

# Study of the Partition Coefficient and the Diffusion Length of Radon in Polymers at Different Temperatures: Experimental Approach and Results

S. Georgiev, K. Mitev, Ch. Dutsov, T. Boshkova, I. Dimitrova  
SUBG

# Polymer membranes

- Radon/Thoron discrimination in lots of passive detectors
- Radon mitigation by water-proofing membranes

Both count on “diffusion delay”  $L_D = \sqrt{\frac{D}{\lambda}} \Rightarrow L_D \sim \sqrt{T_{1/2}}$   
... and  $D$  , resp.  $L_D$  are temperature dependent

# Polymer samplers

- Methods for radon measurements are developed, based on the high radon absorption ability in polymers such as Makrofol DE and N
- The absorption could be described by the partition coefficient  $K$  and the diffusion length  $L_D$  and they both depend on the temperature

# Model of RNG transport in polymers

- At the border polymer/ambient media the RNG concentration ratio is:

$$K = \frac{C_{in}}{C_{out}}$$

- Once in the polymer, the radioactive noble gas (RNG) diffuses and decays:

$$\frac{\partial c}{\partial t} = D \frac{\partial^2 c}{\partial x^2} - \lambda c$$

Sorption and desorption of radioactive noble gases in polycarbonates

D. Pressyanov \*, K. Mitev, S. Georgiev, I. Dimitrova

Department of Atomic Physics, St. Kliment Ohridski University of Sofia, 5 James Bourchier Blvd., 1164 Sofia, Bulgaria

# Model of RNG transport in polymers

- And the absorbed activity in thin plate is:

$$A(t_s, t_d) = \frac{8\lambda L_D^2 V K C_A}{L^2} \sum_{k=0}^{\infty} \frac{e^{-\lambda t_s} - e^{-\lambda_k t_s}}{\lambda_k - \lambda} e^{-\lambda_k t_d},$$

$$\lambda_k = \lambda \left( 1 + \left( \frac{(2k+1)\pi L_D}{L} \right)^2 \right),$$

$\lambda$  – RNG decay const.

$L, V$  – plate thickness and volume

$C_A$  – ambient RNG concentration at  $t_s=0$

$t_s, t_d$  – sorption and desorption time

# Method for estimation of $K$ and $L_D$

- The absorbed-activity equation could be rewritten:

$$A(t_d; K, L_D) = 8VC_AK \sum_{n=1}^{\infty} \frac{e^{-\lambda t_s} - e^{-\lambda \left(1 + (n\pi)^2 \left(\frac{L_D}{L}\right)^2\right) t_s}}{(n\pi)^2} e^{-\lambda \left(1 + (n\pi)^2 \left(\frac{L_D}{L}\right)^2\right) t_d}$$

$n = (2k + 1)$  – an odd number

## DETERMINATION OF THE DIFFUSION COEFFICIENT AND SOLUBILITY OF RADON IN PLASTICS

D. Pressyanov\*, S. Georgiev, I. Dimitrova, K. Mitev and T. Boshkova

Faculty of Physics, University of Sofia 'St. Kliment Ohridski', 5 James Bourchier Blvd, 1164 Sofia, Bulgaria

# Desorption follow-up: challenges

- Temperature have to be constant
  - During both sorption and desorption
  - Including the activity measurement
- Desorption could be fast – depending on  $L_D/L$  it could take a few minutes
  - Fast and precise timing
- Secular equilibrium between Radon/SLP is needed
  - Radon is measured by its short-lived progeny (SLP)
  - So the fast desorption must be “stopped” for the measurement duration (or somehow accounted...)

# Desorption follow-up: challenges

- LSC with toluene cocktail is the best decision for Makrofol N – its fully dissolved in toluene
  - ...but doesn't work for the other polymers
    - Makrofol DE is only partially dissolved in toluene
    - PP, HDPE, LDPE not dissolved at all in toluene and other organic solvents: Gasoline, Bensol(Benzene), 1,2-Dichloroethane (ethylene dichloride)
    - Activity desorbs in the cocktail and the cocktail (or at least toluene) is absorbed in the polymers
- => ***Complicate change in the Counting efficiency***

# Desorption follow-up: challenges

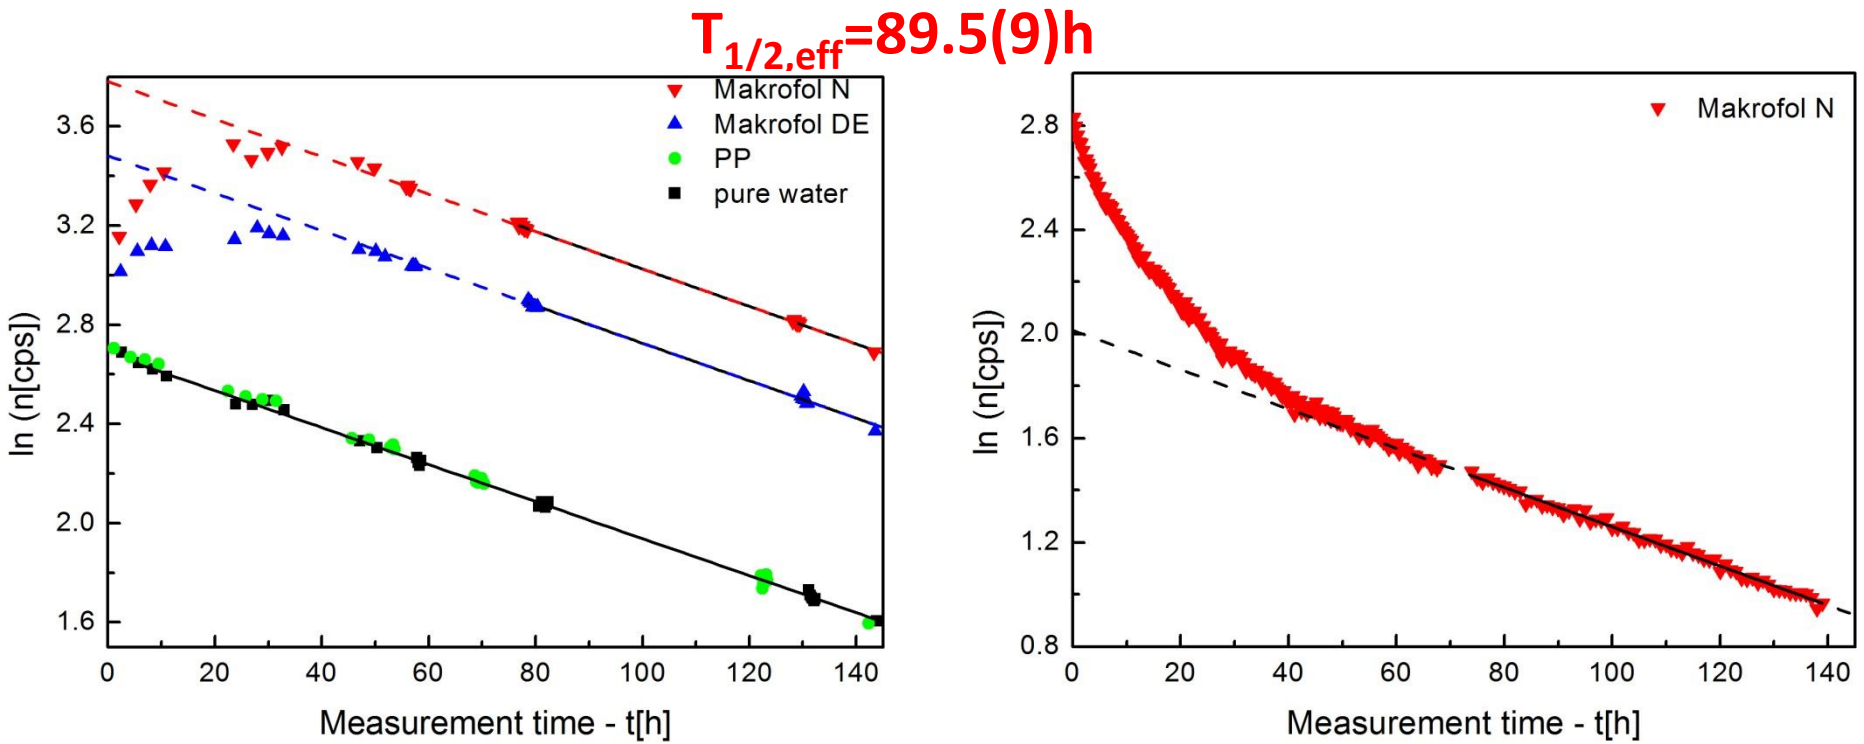

- Cherenkov counting in water:

- + Allows precise timing
  - + Almost fully stops the activity loss during the measurement and allows a posteriori correction
  - + No temperature control during the measurement
  - + One point of the desorption could be measured more than once
- 
- Radon desorbs in the water until equilibrium of radon concentration in the two media is reached
- ⇒ Change of the efficiency during that process
- Each point of desorption is a different foil

# Counting efficiencies $\varepsilon_c$

- Two experiments for  $\varepsilon_c$  estimation:
  - Unexposed foils in high-activity water for better counting statistics
  - Exposed Makrofol N in distilled water – to compare with the previous experiment

# Counting efficiencies $\varepsilon_c$

- Samples are followed at the RackBeta LS-counter and measured several times at HPGe
  - No time dependence of  $\varepsilon_c$  for PP, LDPE, HDPE
  - After 60-70h  $\varepsilon_c = \text{const}$  for Makrofol

No	Sample	Counting efficiency
1	PP in water	0.380(12)
2	LDPE in water	0.371(12)
3	LDPE-A in water	0.400(14)
4	HDPE in water	0.407(13)
5	Makrofol N in water	1.168(36)
6	Makrofol DE in water	0.883(29)
7	pure water	0.376(12)
8	Makrofol N in LSC	4.946(29)

# $K$ , $L_D$ experiments: Exposure setup

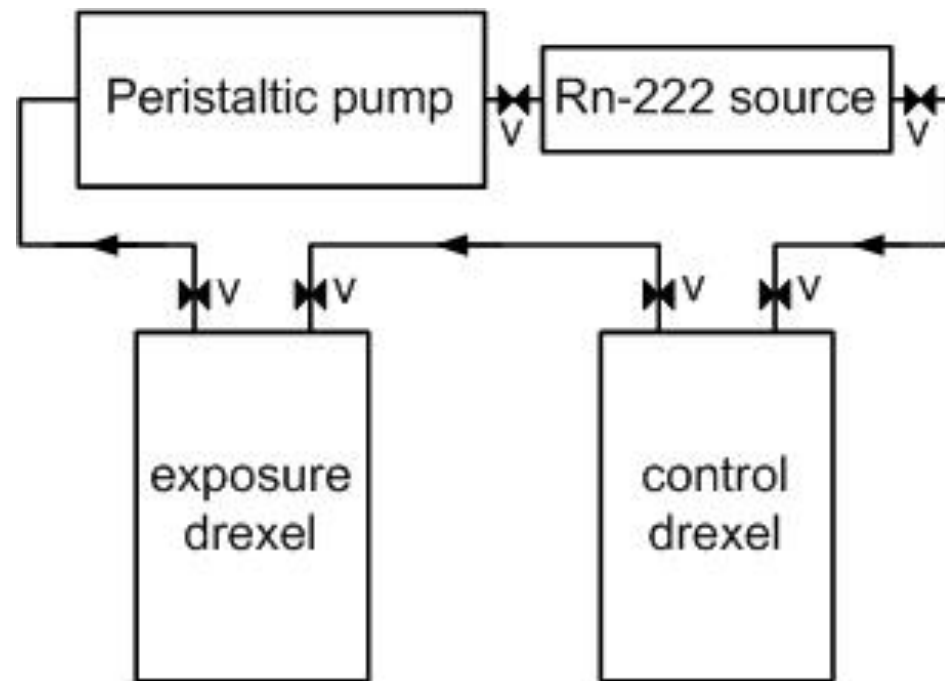

- Six foils 5.6cm x 1.6cm of each material:  
PP, LDPE, LDPE-A, HDPE, Makrofol DE, Makrofol N

# $K, L_D$ experiments: Exposure setup

- Three experiments with very high activity in small volume at 5°C, 21°C and 31°C
  - High  $C_A$  to ensure better counting statistics
  - and longer desorption follow-up

*Rn is promptly introduced in the system in the beginning and the system is disconnected*

*The activity from the control drexel is diluted and measured, in order to estimate the exposure  $C_A$*

# $K, L_D$ experiments: Exposure setup

- During the exposure, the exposure drexel was placed in the 50L box, and the 50L box was placed in thermostate for temperature control
- The activity concentration in the 50L box was measured in order to check for activity leakage
  - The leakage was found to be less than 1% in all experiments
- After the exposure the foils were kept in the thermostate, in order to desorb at the same temperature

# $K$ , $L_D$ experiments: Exposure setup

- One experiment in the 50L referent volume of the AlphaGuard at 10°C
  - Due to much lower  $C_A$ , only Makrofol foils were used
  - The foils were stuck in the holder and placed directly in the 50L volume
  - $C_A$  was measure directly
  - 6 Makrofol DE and 12 Makrofol N foils were used
  - 6 Makrofol N were measured in toluene and the other 6 – in water
